In January 2020, the World Health Organization (WHO) announced the COVID-19 outbreak, caused by SARS-CoV-2, a public-health emergency [1]. Following the skyrocketing spread of SARS-CoV-2 into more than 210 countries, diverse clinical strategies have been urgently explored against the COVID-19 pandemic while a magic-bullet antiviral vaccine or treatment is unavailable [2]. Although the clinical features of COVID-19 and the epidemiological characteristics of the pandemic have been described, COVID-19 has seemingly evolved, and its new symptoms and associations are being reported over time [3-7]. Nevertheless, SARS-CoV-2 is extremely contagious and new to the human immune system; thus, everyone is vulnerable.

Though many affected by SARS-CoV-2 had shown mostly mild symptoms and many have recovered, a considerable proportion of patients would likely suffer from severe life-threatening symptoms and poor prognoses. For example, individuals with cardiovascular diseases or chronic pulmonary diseases constitute a high-risk group, sadly showing a high mortality rate and poor prognoses. Presently, no sophisticated clinical trial is underway to test the potential side-effects of the presently prescribed medications in the COVID-19 patients (for example, administration of inhibitors of angiotensin-converting enzyme 2 [ACE2] and angiotensin II receptor blockers)

[8-10]. Thus, such recommendations should be considered carefully because of the likely emergence of the cardiovascular toxicity [11].

ACE2 is a dipeptidyl carboxypeptidase expressed on the surface of endothelial cells, intestinal cells, renal glomerular and tubular cells, and cardiac myocytes and pericytes [12-16]. ACE2 is highly expressed in the pulmonary type-II alveolar cells [13] and functions as part of the renin—angiotensin—aldosterone system. This system begins with angiotensinogen, which is produced in the liver and released into the bloodstream. First, renin secreted by the renal juxtaglomerular apparatus converts angiotensinogen to angiotensin I. Then, the latter is converted into angiotensin II by angiotensin-converting enzyme, ACE, which is mainly produced in the lungs. Next, angiotensin II binds to the angiotensin II type 1 receptor on the surface of blood vessels (lung, and myocytes among others) to act as a vasoconstrictor and regulate inflammation and immune responses [17].

On the other hand, activation of angiotensin II type 2 receptor by angiotensin II causes vasodilation. Meanwhile, cell-surface ACE2 is cleaved and activated by ADAM metallopeptidase domain 17. In parallel, active ACE2 is released into the interstitial spaces where it converts angiotensin I to angiotensin 1-9 and angiotensin II to angiotensin 1-7 which binds to MAS receptors and

causes the counter-regulatory function, i.e., vasodilation. Vasoconstriction causes hypertension, which may contribute to acute respiratory distress syndrome [17, 18]. Based on the understanding of this system, excess recombinant ACE2 has been proposed to lure the virus into binding it instead of binding cell-surface ACE2. Luring the virus is then thought to protect the endogenous ACE2 to counterbalance the function of ACE, ideally protecting against viral damage to the lung and heart [19].

Accordingly, on April 2, 2020, Apeiron Biologics was awarded a regulatory authorization [19] to initiate the phase II clinical trials for testing APN01 on 200 patients with severe COVID-19 symptoms. This rationale is in contrast to using ACE2 inhibitors because APN01 is the recombinant human ACE2 that could potentially lure SARS-CoV-2 away from entering into its target cells and reduce lung injury when circulating in excess in the bloodstream and interstitial spaces. This proposal was tested in a cell-culture model with positive results [20]. Besides vasoregulation, ACE2 binds to the neutral amino acid transporter B⁰AT1 (SLC16A19) to facilitate the cell-surface expression of this transporter on the luminal surface of intestinal epithelial cells. Based on this interaction, ACE2 deficiency has been shown to critically impair tryptophan and nicotinamide homeostasis in mice [21]. Also, it increases the susceptibility to intestinal inflammation and colitis, changes the composition of the intestinal microbiome, and alters the expression of some antimicrobial peptides [21]. Thus, any proposed therapy using ACE2 inhibitors will potentially have gastrointestinal, renal, cardiac, pulmonary, and metabolic implications [5, 8, 11, 12, 18, 20-23].

High rates of cardiac effects were reported by Chen et al. when ≈75 out of 99 COVID-19 patients presented with high levels of lactate dehydrogenase [24]. Collapsing glomerulopathy has recently been studied and reported in one case [7]. While the initial data were reported of patients who were admitted to a hospital in Wuhan, Hubei Province, China, collective data from other countries—especially from Iran, Italy, South Korea, and the United States—now present an evolving picture of the viral pathogenesis, recently presenting with rare symptoms similar to toxic shock and Kawasaki disease in young children [5, 22].

Antiviral therapy, immunotherapy, anti-inflammatory therapy, and application of prophylactic vaccines have been recommended in the management of COVID-19, but no definitive intervention has been validated to treat the patients. How SARS-CoV-2 infection directly affects the cardiovascular system is unknown while acute and

chronic cardiac damage, ventricular dysfunction, heart failure, arrhythmias, and acute coronary syndromes have been reported [11, 23]. Furthermore, the other pathogenic mechanisms underlying this viral infection are largely unclear. Thus, it is risky to administer any untested intervention to urgently treat the vulnerable COVID-19 patients with comorbid cardiovascular diseases, chronic pulmonary diseases, or gastrointestinal conditions.

Using the ACE2 inhibitors in such patients has not been validated, and further research is needed to achieve useful evidence-based facts for directing therapy. Despite the fast pace of the pandemic, any recommended treatment must first pass initial clinical and para-clinical testing.

Ethical Considerations

Compliance with ethical guidelines

All ethical principles were considered in this article.

Funding

This research did not receive any grant from funding agencies in the public, commercial, or non-profit sectors.

Authors contribution's

Both authors contributed equally in preparing all parts of the research.

Conflict of interest

The authors declared no conflict of interest.
